

Basic build (1-4)

1. Initial solution

Python solution over the original FinQA tables establishes the logic

2. Backing data store

SQLite tables are generated to model the scenario; hold the answer-relevant records

3. Basic tools

Tool functions are written as abstractions over the backing store

4. Correct plan (basic)

Reference solution written using only the basic tools

Augmentation (5-7)

7. Correct plan (augmented)

Reference solution rewritten over the augmented tools (multi-hop path)

6. Augmented tools

Extended toolkit: core tools, partial-information chains, distractor tools

5. Augmented backing store

Store is expanded with additional tables, split data, and distractor rows

Packaging (8-9)

8. System prompt

Scenario description and tool definitions; the backing table data is excluded

9. Agent code

Runnable smolagents agent ready for evaluation

Final dataset (1,108 examples)

Each stage is validated by execution; failures are retried up to 10 times before the example is dropped.
